

antVacDB extraction agent — components (2026-06-04)

one paper-dir in → one validated *_extracted.json out · sandboxed Claude Agent SDK · slim prompt · incremental on-disk assembly

What changed vs the original scaffold

- Prompt slimmed 84KB → ~20KB: embeds a generated schema DIGEST, not the full source; deltas trimmed of engineer/version prose.
- Sandboxed: host config/hooks/skills excluded; the agent can ONLY call the antvac tools (no escaping to Bash).
- Save is incremental + on-disk (init → add → finalize), so big records build across turns and survive context compaction.
- add_table does deterministic bulk row→entity transcription – the fix for hand-typing ~700 entities blowing the turn budget.
- Scaling unchanged: one SLURM array task per paper-dir → reducer ingests (pass → DB, fail → quarantine); quarantine rate = health.

read_figure = 2-step vision (page→crop, conservative record) · validate/save_extraction kept but deprecated · schema.py never edited (contract is canonical)
